ABSTRACT

A grand challenge in the post-genomic era is a complete computer representation of the cell and the organism, which will enable computational prediction of higher-level complexity of cellular processes and organism behavior from genomic information. Toward this end we have been developing a knowledge-based approach for network prediction, which is to predict, given a complete set of genes in the genome, the protein interaction networks that are responsible for various cellular processes. KEGG at <http://www.genome.ad.jp/kegg/> is the reference knowledge base that integrates current knowledge on molecular interaction networks such as pathways and complexes (PATHWAY database), information about genes and proteins generated by genome projects (GENES/SSDB/KO databases) and information about biochemical compounds and reactions (COMPOUND/GLYCAN/REACTION databases). These three types of database actually represent three graph objects, called the protein network, the gene universe and the chemical universe. New efforts are being made to abstract knowledge, both computationally and manually, about ortholog clusters in the KO (KEGG Orthology) database, and to collect and analyze carbohydrate structures in the GLYCAN database.

INTRODUCTION

KEGG (Kyoto Encyclopedia of Genes and Genomes) is a bioinformatics resource for understanding higher-order functional meanings and utilities of the cell or the organism from its genome information. It is an integrated resource consisting of three types of database for genomic, chemical and network information, and associated software, which are all developed by the Kanehisa Laboratory (now part of the Bioinformatics Center) in the Institute for Chemical Research, Kyoto University. While KEGG has cross-references to numerous outside databases, it is intended to be a self-sufficient system for linking genomes to life at the cellular level, containing a complete set of building blocks (genes and molecules) and wiring diagrams (interaction networks) for cellular functions. Eventually, this self-sufficient system will become a computer

representation of the cell and the organism, and perhaps the biosphere as well, which will enable *in silico* analysis of biological systems (1). Even at the current primitive stage, KEGG is widely used for analysis of various types of molecular biological data in order to obtain clues to higher-order functions.

During the past 2 years we have worked to make the KEGG resource (2,3) more accessible to automated analysis. For example, the XML representation of KEGG pathway diagrams is useful for automatic drawing of potential networks identified by two-hybrid experiments as an extension to known networks. Access to KEGG can now be made through the KEGG API (SOAP interface to KEGG), which means that the user can write a program to analyze microarray gene expression data or to annotate a newly sequenced genome by automating KEGG queries. In addition, we have released two new database components: KO for ortholog grouping and hierarchical classification of genes and GLYCAN for carbohydrate structures. Here we describe the current status and future plans of the KEGG resource.

THE KEGG DATABASES

Graph representation

To understand the overall architecture, it is useful to know that KEGG consists of three graph objects for representation and manipulation of genomic, chemical and network data. Mathematically, a graph is a set of nodes (building blocks) and edges (interactions or relations). As shown in Table 1 the three graph objects are called the gene universe (GENES, SSDB and KO databases), the chemical universe (COMPOUND, GLYCAN and REACTION databases), and the protein network (PATHWAY database). The gene universe is a conceptual graph object representing ortholog/paralog relations, operon information and other relationships between genes in all the completely sequenced genomes. The chemical universe is another conceptual graph object representing chemical reactions and structural/functional relations among metabolites and other biochemical compounds. In contrast, the protein network is based on biological phenomena, representing known molecular interaction networks in various cellular processes (2).

Network hierarchy

Another important aspect in the overall architecture of KEGG is network hierarchy. The protein network, which is the most unique data object in KEGG, is stored as a collection of

01400 Cellular processes
01500 Human disease

pathway maps in the PATHWAY database, representing wiring diagrams of proteins and other gene products responsible for various cellular functions. Reflecting the map resolution and functional modules at different levels, these pathway maps are hierarchically classified. There are five categories in the top level (metabolism, genetic information processing, environmental information processing, cellular processes and human diseases) and 24 subcategories in the second level. The third level in the hierarchy corresponds to individual pathway maps. When the protein network is linked to the gene universe, the fourth level corresponds to KO (KEGG Orthology) entries. Thus the hierarchy of gene functions in KEGG is based on the hierarchy of the protein network as shown in Table 2.

GENE UNIVERSE

GENES database

The information about individual genes is stored in the GENES database. As of September 12, 2003 the GENES

database contains 572 881 genes in 155 organisms. The GENES entries are generated semi-automatically by selecting and combining various sources including authors' submissions to GenBank (<ftp://ftp.ncbi.nih.gov/genbank/genomes/>), the NCBI RefSeq database (<ftp://ftp.ncbi.nih.gov/genomes/>), the EMBL database (<ftp://ftp.ebi.ac.uk/pub/databases/embl/genomes/>) and publicly available organism-specific databases. They are then subjected to internal re-annotation, in which we just assign K numbers for the KO grouping of genes without updating the description of the genes. Our KO assignment appears in the ORTHOLOG line of the GENES entry.

SSDB database

SSDB was originally a sequence similarity database containing precomputed similarity scores by the SSEARCH program with additional information about best hits and best-best hits in pairwise genome comparisons (2). We have recently implemented an automatic procedure, based on a graph analytical method, to computationally generate ortholog clusters (OCs) and paralog clusters (PCs) from the huge

resulting from direct protein–protein interactions, but also the metabolic network viewed as a network of enzymes, and the gene regulatory network viewed as a network of transcription factors and target products (2,3). The PATHWAY database is a collection of manually drawn diagrams called the KEGG reference pathway diagrams (maps), each corresponding to a known network of functional significance. The PATHWAY database also contains organism-specific pathways, which are automatically generated by superimposing (coloring) genes in given organisms. The database currently contains 13 457 entries including 235 reference pathway diagrams.

In the past, the pathway diagrams were available only in GIF (or PNG) image files. Although the coordinates of nodes (boxes) could be obtained from the HTML file, it was not possible to reconstruct the pathway because the edge information was not readily available. We have released the KEGG Markup Language (KGML) as a specification of graph objects in KEGG. All metabolic pathways and some regulatory pathways are now available in KGML, enabling computational reconstruction and manipulation of KEGG pathways.

ACCESS METHODS

The primary mode of access to KEGG is through the GenomeNet website at <http://www.genome.ad.jp/kegg/>. Different components of the KEGG resource can most conveniently be accessed from the KEGG table of contents page at <http://www.genome.ad.jp/kegg/kegg2.html>. The four databases for the chemical universe, COMPOUND, GLYCAN, REACTION and ENZYME are collectively called the LIGAND database with a separate home page at <http://www.genome.ad.jp/ligand/>. Table 3 summarizes these and

other useful URLs including additional databases not covered in the present article.

For computerized access to KEGG, the SOAP server is open to academic users at <http://www.genome.ad.jp/kegg/soap/>. All the KEGG databases, except SSDB, are also available to academic users by anonymous FTP at <http://www.genome.ad.jp/anonftp/>.

ACKNOWLEDGEMENTS

The computational resource was provided by the Bioinformatics Center, Institute for Chemical Research, Kyoto University. This work was supported by grants from the Ministry of Education, Culture, Sports, Science and Technology of Japan, the Japan Society for the Promotion of Science and the Japan Science and Technology Agency.
